

## DIMENSIONING

## Multi Mode Calculations

According to the example, mentioned on page 44, it is requested to establish a fiber connection between to distribution frames, with a distance of 200 meters between the two distribution frames. It is also requested to use drop - and patch cables at both ends. The required speed is 1Gbit. Due to the patch cables, we shall need three pairs of connectors.

## Losses

| Fiber Loss (at 850nm) | $2,5 \mathrm{~dB}$ pr Km | $0,5 \mathrm{~dB}$ |
| :--- | :--- | :--- |
| Connector loss | $0,4 \mathrm{~dB}$ pr. pairs | $1,2 \mathrm{~dB}$ (3 pairs) |
| Splicings, if necessary | $0,05 \mathrm{~dB}$ pr. splicing |  |
|  |  |  |
| Expected Loss |  | $1,7 \mathrm{~dB}$ |
| Reserve for repairs,if necessary |  | $3,0 \mathrm{~dB}$ |

In other words, we will need a pair of media converters with a budget of at least $4,7 \mathrm{~dB}$.

Below, an example from Transition
Figure 1

There are different kinds of media converter modules, capable of different distances. Assuming a speed of 1 Gbit, distances up to 2 kilometers will be possible, by using multi mode fiber. If we use single mode fiber in stead, the maximum distance may be increased to 125 kilometers.

$$
\begin{aligned}
& \text { 1000BASE-T (RJ-45) [100 m/328 ft.] } \\
& \text { 1000BASE-SX 850nm MM (SC) } \\
& 220 \mathrm{~m} / 722 \mathrm{ft} \text { ) Link Budget: } 7.0 \mathrm{~dB} \\
& 550 \mathrm{~m} / 1804 \mathrm{ft} \text { ) Link Budget: } 7.0 \mathrm{~dB}
\end{aligned}
$$

This converter can manage distances between 220 and 550 meters. If you use $62,5 \mu \mathrm{~m}$ fiber, the distance will be only 220 meters. If you on the other hand use $50 \mu \mathrm{~m}$ fiber (which, over time, has become the most commonly used fiber), the distance will be 550 meters. With regard to losses there is a total budget of 7 dB , that is, no problems at all.

## Single Mode Calculations

Let us take another example. It is requested to establish a fiber connection between two distribution frames, placed in separate buildings. The distance between the distribution frames is 30 km . Drop - and patch cables will be used at both ends. The requested speed is 1 Gbit . Due to the patch cables at both ends, 3 pairs of connectors must be included.

| Fiber loss (at 1310nm) | $0,4 \mathrm{~dB}$ pr. km | 12 dB |
| :--- | :--- | :--- |
| Connector loss | $0,4 \mathrm{~dB}$ pr. pairs | $1,2 \mathrm{~dB}$ (3 pairs) |
| $\mathbf{6}$ splicings | $0,05 \mathrm{~dB}$ pr. <br> splicing | $0,3 \mathrm{~dB}$ |
|  |  |  |
| Expected loss |  | $13,5 \mathrm{~dB}$ |
| Reserve for repairs, if necessary |  | $3,0 \mathrm{~dB}$ |
| Total budget |  | $16,5 \mathrm{~dB}$ |

The reason for the 6 splicings in the budget is due to the fact, that you can not buy fiber drums longer than 5-8 kilometers as the cable drum otherwise would become too big.

Figure 2

As you can see, the installation is the same as in figure 1.

$$
\begin{aligned}
& \text { 1000BASE-T (RJ-45) [100 m/328 ft.] } \\
& \text { 1000BASE-LX 1550nm SM (SC) } \\
& \text { [65 km/40.4 mi.] Link Budget: } 21.0 \mathrm{~dB}
\end{aligned}
$$

Using the information in the table above, it is possible to calculate a budget for a distance of 30 kilometers. If we have a media converter budget of 21 dB and a consumption of $16,5 \mathrm{~dB}$, we do not have any problems at all. The 100 meters, referred to in the table, is the copper connection. The length of the copper connection must not exceed 100 meters ( 90 meters of fixed wiring).
